

application NOTE

Sedona 1.2 Component Descriptions

Developed by Tridium Inc., Sedona Framework™ is a software environment designed to make it easy to build smart, networked, embedded devices which are well suited for implementing control applications. The system integrator's role is to create an application by assembling components onto a wire sheet using graphical programming tools such as Niagara Workbench or a third-party Sedona Tool. Applications are then executed by a Sedona Virtual Machine (SVM) resident in Contemporary Controls' BASremote or BAScontrol family of controllers.

Components are deployed in kits which are available from Tridium, Contemporary Controls and other members of the Sedona community. Kits without a company name are from Tridium. Kits with a company name and no product name are from a Sedona community member and these components can be used with other Sedona

devices. Kits with both a company name and product name are hardware dependent thereby limiting portability. What follows are both standard and custom components compliant with Sedona release 1.2.28. These components are organized by kit name.

When studying these components keep the following in mind. Boolean variables are assumed if there is a false/true state indication. Integers (32-bit signed integers) are shown as whole numbers while floats (32-bit floating point) are shown with a decimal point. Many of the following components may have been expanded in order to show all component slots in order to display configuration detail. The default view of these components on a wire sheet may not show the same level of detail. The standard Tridium components are shown first and it is Contemporary Controls' policy not to modify Tridium released components.

Index of Kits

Basic Schedule Kit (basicSchedule)

DailySchedule represents a simple daily schedule with up to two active periods. Each active period is defined by a start time and duration. If the duration is zero, the period is disabled. If the periods overlap, then the first period (defined by *Start1* and *Dur1*) takes precedence. If the duration extends past midnight, then the active period will span two separate calendar days. There are two components in the kit — one for Boolean outputs and the other for floats. Both kits rely upon the time being set in the target hardware.

Duration periods — *Dur1* and *Dur2* — are configured in minutes from zero to 1439 minutes.

DailySc	
basicSchedule::DailyScheduleBool <input type="radio"/>	
Start1	0 min
Dur1	0 min
Start2	0 min
Dur2	0 min
Val1	false
Val2	false
Def Val	false
Out	false

Daily Schedule Boolean — two-period Boolean scheduler.

Configure *Def Val* to the intended output value if there are no active periods. Configure *Val1* and *Val2* for the desired output values during period 1 and period 2 respectively.

Out = *Def Val* if no active periods

Out = *Val1* if period 1 is active

Out = *Val2* if period 2 is active

DailyS1	
basicSchedule::DailyScheduleFloat <input type="radio"/>	
Start1	0 min
Dur1	0 min
Start2	0 min
Dur2	0 min
Val1	0.00
Val2	0.00
Def Val	0.00
Out	0.00

Daily Schedule Float — two-period float scheduler.

Configure *Def Val* to the intended output value if there are no active periods. Configure *Val1* and *Val2* for the desired output values during period 1 and period 2 respectively.

Out = *Def Val* if no active periods

Out = *Val1* if period 1 is active

Out = *Val2* if period 2 is active

Date Time STD Kit (datetimeStd)

DateTim	
datetimeStd::DateTimeServiceStd 	
Nanos	1378541000000000 ns
Hour	22
Minute	55
Second	41
Year	2000
Month	1
Day	16
Day Of Week	0
Utc Offset	0 s
Os Utc Offset	false

The *DateTim* component is the only component in the Date Time STD Kit. This component relies upon a properly functioning real-time clock implemented in hardware. Once date and time are configured, this component can be dragged onto a worksheet allowing individual integer outputs to be wired to logic if so desired. However, it is not necessary to have the component on the wiresheet at all. If the *DailySchedule* components are to be used, they will function properly without the presence of the *DateTim* component. The start and stop times in the *DailySchedule* key on the daily time generated by the *DateTime* component regardless if this component is on the wiresheet.

Please Note

By double clicking the DateTim component, you will see the setup screen below. When using Contemporary Controls' controllers, make sure that the Use System Offset option is selected as shown. To avoid confusing time settings, do not set the time with this component. Set the time using the Set Time web page on the controller which provides more flexibility. You can set time zone, daylight saving time and in some instances Network Time Protocol support using just the web page. These settings will then set this Sedona component properly.

DateTimeService
Manage system clock for device

	Current	Desired
Current Time	<input type="text" value="27-May-2015 17:34:41 Wed"/>	<input type="text" value="27-May-2015 05:34 PM CDT"/>

Function Kit (func)

Cmpr	
func::Cmpr	
Xgy	false
Xey	true
Xly	false
X	0.00
Y	0.00

Comparison math — comparison (<=>) of two floats.

If $X > Y$ then Xgy is true

If $X = Y$ then Xey is true

If $X < Y$ then Xly is true

Count	
func::Count	
Out	0
In	false
Preset	0
Dir	up
Enable	false
R	false

Integer counter — up/down counter with integer output.

Counts on the false to true transition of *In*. If *Dir* = true the counter counts up to the maximum value of the integer. If *Dir* = false the counter counts down but not below zero. For counting to occur, *Enable* must be true. The counter can be preset. If *R* = true and *Enable* = true, then *Out* equals the preset value and will not count.

Freq	
func::Freq	
Pps	0.000 /s
Ppm	0.000 /min
In	false

Pulse frequency — calculates the input pulse frequency.

Pps = number of pulses per second of In

Ppm = number of pulses per minute of In

Hystere	
func::Hysteresis	
In	0.00
Out	false
Rising Edge	50.00
Falling Edge	50.00

Hysteresis — setting on/off trip points to an input variable.

There are two internal floats called *Rising Edge* and *Falling Edge* which are configurable. If *Rising Edge* is greater than *Falling Edge*, then the following is true.

If $In > Rising\ Edge$ then $Out = true$ and will remain in that state until $In < Falling\ Edge$

If $Rising\ Edge$ is less than $Falling\ Edge$ then the action is inverted.

IRamp	
func::IRamp	
Out	77
Min	0
Max	100
Delta	1
Secs	1 s

IRamp — generates a repeating triangular wave with an integer output.

There are four configurable float parameters — *Min*, *Max*, *Delta* and *Secs*. For every scan cycle, the output increments by *Delta* units until the output equals the *Max* value at which time it decrements until *Min* is reached. The result is a triangular wave with limits of *Max* and *Min* and an incremental rate of *Secs* units.

Limiter	
func::Limiter	
Out	0.00
In	0.00
Low Lmt	0.00
High Lmt	0.00

Limiter — Restricts output within upper and lower bounds.

High Lmt and *Low Lmt* are configurable floats.

If $In > High\ Lmt$ then $Out = High\ Lmt$

If $In < Low\ Lmt$ then $Out = Low\ Lmt$

If $In < High\ Lmt$ and $> Low\ Lmt$ then $Out = In$

Application Note — Sedona 1.2 Component Descriptions

Linearize	
func::Linearize	
Out	nan
In	0.00
X0	0.00
Y0	0.00
X1	0.00
Y1	0.00
X2	0.00
Y2	0.00
X3	0.00
Y3	0.00
X4	0.00
Y4	0.00
X5	0.00
Y5	0.00
X6	0.00
Y6	0.00
X7	0.00
Y7	0.00
X8	0.00
Y8	0.00
X9	0.00
Y9	0.00

Linearize — piecewise linearization of a float.

For piecewise linearization of a nonlinear input, there are ten pairs of x,y parameters that must be configured into this component. The x,y pairs indicate points along the input curve. For an x value of the input, there should be a corresponding y value of the output. For input values between these points, the component will estimate the output based upon the linear equation:

$$Out = y = y_0 + (y_1 - y_0) \frac{x - x_0}{x_1 - x_0}$$

where y is the value for input value x between coordinates x_0, y_0 and x_1, y_1

LP	
func::LP	
Enable	true
Sp	0.00
Cv	0.000
Out	0.00
Kp	1.000000
Ki	0.000000 /min
Kd	0.000000 s
Max	100.000000
Min	0.000000
Bias	0.000000
Max Delta	0.000000
Direct	true
Ex Time	1000 ms

LP — proportional, integral, derivative (PID) loop controller.

The LP component is much more complex component requiring an explanation of the numerous configurable parameters. *Sp* is the *setpoint* or the desired outcome. *Cv* is the *controlled variable* which we are trying to make equal to the setpoint. The difference between *Cv* and *Sp* is the *error signal (e)* that drives the *output variable Out* used to manipulate the *controlled variable*. There are three gain factors *Kp, Ki, Kd* — called *tuning parameters* — for each of the three modes of the controller: *proportional, integral and derivative*. Setting a gain factor to zero effectively disables that particular mode. Setting *Kp* to zero would completely disable the controller. Typical controller operation is either:

Proportional-only (P)

Proportional plus reset (integral) (PI)

Proportional plus reset plus rate (PID)

In HVAC applications, P and PI are the most common. PID is seldom used.

Enable must be set true if loop action is to occur. If *Enable* is set to false, control action ceases and the output will remain at its last state. However, if *Ki* or *Kd* are non-zero, internal calculations will continue.

If *Direct* is equal to *true*, then the output will increase if the *Cv* becomes greater than *Sp*. If this was a temperature loop, this would be considered being in *cooling mode*. If *Direct* is equal to *false*, then the output will decrease if the *Cv* becomes greater than the *Sp*. If this was a temperature loop, this would be considered being in *heating mode*. Notice that by entering negative gain factors, the action of the controller is reversed.

Application Note — Sedona 1.2 Component Descriptions

Max and *Min* are limits on the output's swing and are considered the absolute boundaries to the controller's throttling range (proportional control range). Basically, the *LP* component includes *Limitter* functionality.

Bias sets the output's offset. Sometimes *bias* is called manual reset to correct an output error with a large proportional band. It is usually only used with proportional-only control. The amount of bias is not influenced by the proportional gain *Kp*. Bias is also used on split-range control systems that will be discussed shortly.

Ex Time is the amount of time in milliseconds that the control loop is solved. Typical times are from 100–1000 ms with a default of 1000. Most HVAC loops are slow acting and therefore solving loops faster brings no benefit.

In the following discussion on setting the gain factors, assume we need a temperature controller enabled for direct action and that the output can swing from –50% to +50%. When the output ranges from 0 to 50%, a proportional cooling valve is modulated. When the output ranges from 0 to –50%, a proportional heating valve is modulated. At 0% output no valve is open. This is called a split range control system. *Max* and *Min* are set to –50 and +50 respectively. When we force the controller output from maximum heat to maximum cooling (100% output change), we notice that we can effect a change in our process temperature of 20°. This becomes our throttling range. In the real world, conducting this test might be difficult.

Now we need to set the three tuning parameters. We first begin by setting *Ki* and *Kd* to zero, thereby creating a proportional-only controller. The controller equation therefore becomes:

$$Out = Kp(e) + Bias \quad \text{where } e = Cv - Sp \text{ and Bias equals zero}$$

Our first guess at *Kp* is 5 because we know that a 100% change in output yielded a 20° change in process temperature. This assumes that we can cool with the same efficiency as we can heat which may not be the case. By having a *Kp* of 5, the output will remain linear over this wide range. Notice that if there is no error signal (*Cv-Sp* is equal to zero), the output will then equal the *bias*, but in this case the bias is zero. The value 5 is entered into *Kp* and a disturbance is introduced into the process such as a step change in the setpoint. If the process continues to oscillate between heating and cooling and never settles down, then we must reduce our proportional gain *Kp* which increases our proportional band ($1/Kp$ times 100% is the proportional band). Assume we achieve a stable system with *Kp* at 5 (proportional band at 20%) but based on the load on the system we notice that the output reached 70%. Our setpoint is at 70°, but our controlled temperature is 74°. Temperature is stable, but we have a 4° offset. This is the inherent difficulty with proportional-only control, there is an offset depending upon the value of the output. We have two choices. We can increase the proportional gain to 10 because we do not need a 20° range in input, but we risk oscillation. The second approach is to “reset the output manually” by increasing the bias. Approach one will never solve the problem but will minimize it, and there is a better method to approach two and that is called *automatic reset* — or adding reset action by adding a *Ki* term. The new controller equation becomes:

$$Out = Kp(e + Ki \int e dt) \quad (\text{Bias is disabled when Ki is non-zero.})$$

Application Note — Sedona 1.2 Component Descriptions

If there remains an error signal ($e \neq 0$), then the integral of the error over time will continue to drive the output until the error is driven to zero. The amount of action is determined by the K_i term. Notice that the integral term in the equation is also multiplied by the proportional gain before being applied to the output. The K_i coefficient is defined in units of repeats per minute. Too large a value can cause overshoot while too small a value will make the control system sluggish. The final setting K_p and K_i is done in the field based upon system response.

The third parameter is the rate parameter K_d which acts upon the rate of change of the error signal. Adding this term changes the controller equation as follows:

$$Out = K_p(e + K_i \int e dt + K_d de/dt)$$

For processes with extremely long reaction times, derivative control could be helpful in reducing overshoot. K_d is entered in seconds. As mentioned before, it is seldom used because tuning a control loop with three parameters can be challenging.

There is one more parameter called *Max Delta*. This value limits the output slew rate by restricting the output change each time the control loop is recalculated by the amount entered. This parameter will dramatically reduce the response time of the control loop.

Ramp 	
func::Ramp	
Out	87.48
Min	0.00
Max	100.00
Period	10 s
Ramp Type	triangle

Ramp — generates a repeating triangular or sawtooth wave with a float output.

There are four configurable float parameters — *Min*, *Max*, *Period* and *Ramp Type*. For every scan cycle, the output increments by one unit until the output equals the *Max* value at which time it decrements until *Min* is reached. The result is a triangular wave with limits of *Max* and *Min* if *Ramp Type* is set for triangle. If *Ramp Type* is set for sawtooth, then the output will immediately drop to *Min* when *Max* is reached. The *Period* of the ramp is adjustable.

SRLatch 	
func::SRLatch	
Out	false
S	false
R	false

Set/Reset Latch — single-bit edge-triggered data storage.

The following logic applies on the false-to-true transition of S or R:

If S goes true and R does not change, then Out = true and remains true.

If R goes true and S does not change, then Out = false and remains false.

If both S and R go true on the same scan, then Out = false and remains false.

TickToc 	
func::TickToc	
Out	false
Ticks Per Sec	1 /s

Ticking clock — an astable oscillator used as a time base.

There is one configurable float parameter — *Ticks Per Sec* — which can range from a low of 1 to a high of 10 pulses per sec.

Out = a periodic wave between 1 and 10 Hz

UpDn 	
func::UpDn	
Out	0.00
Ovr	false
In	false
Rst	false
C Dwn	false
Limit	0.00
Hold At Limit	false

Float counter — up/down counter with float output.

The counter range is between zero and a value that can be set with configurable parameter *Limit*. To cease counting at the limit set the configurable parameter *Hold at Limit* to true. To count down instead of up, set *C Dwn* to true. To reset the counter to zero set *Rst* to true. *Ovr* is the overflow indicator. *In* is the Boolean count input.

Out = the current count

If Out ≥ Limit then Ovr is true

HVAC Kit (hvac)

LSeq 	
hvac::LSeq	
In	0.00
In Min	0.00
In Max	100.00
Num Outs	16
Delta	5.88
D On	0
Out1	false
Out2	false
Out3	false
Out4	false
Out5	false
Out6	false
Out7	false
Out8	false
Out9	false
Out10	false
Out11	false
Out12	false
Out13	false
Out14	false
Out15	false
Out16	false
Ovfl	false

Linear Sequencer — bar graph representation of input value.

There are two internally configurable floats called *In Min* and *In Max* that set the range of input values. An internal configurable integer — called *Num Outs* — specifies the intended number of active outputs. By dividing the input range by one more than the number of active outputs, the *Delta* between outputs is determined. Outputs will turn on sequentially from *Out1* to *Out16* within the input range as a function of increasing input value.

For example: *In Min* is set to 0, *In Max* to 100, and *Num Outs* is set to 9. This would give a *Delta* of 10. The following is true for increasing values of the input:

If In = 9 then Out1–16 are false and D On is zero.

If In = 70 then Out1–7 are true and Out8–16 are false. D On is 7.

If In = 101 then Out1–9 are true and Out10–16 are false. D On is 9 and Ovfl is true.

Note that for decreasing values of the input, the outputs will change by a value of $\Delta/2$ below the input values stated above.

ReheatS 	
hvac::ReheatSeq	
Out1	false
Out2	false
Out3	false
Out4	false
In	0.00
Enable	false
D On	0
Hysteresis	0.00
Threshold1	0.00
Threshold2	0.00
Threshold3	0.00
Threshold4	0.00

Reheat Sequence — linear sequence up to four outputs.

There are four configurable threshold points — *Threshold1* through *Threshold4* — that determine when a corresponding output will become true as follows:

Out1 = true when In ≥ Threshold1

Out2 = true when In ≥ Threshold2

Out3 = true when In ≥ Threshold3

Out4 = true when In ≥ Threshold4

These outputs will remain true until the input value falls below the corresponding threshold value by an amount greater than the configurable parameter *Hysteresis*. Output signal *D On* indicates how many outputs are true. Configurable parameter *Enable* must be true otherwise all outputs will be false.

Reset	
hvac::Reset	
Out	0.00
In	0.00
In Min	0.00
In Max	4095.00
Out Min	0.00
Out Max	100.00

Reset — output scales an input range between two limits.

There are four configurable float parameters — *In Max*, *In Min*, *Out Max* and *Out Min* — which determine the input and output ranges respectively of the input and output. The output of this component will scale linearly with the value of the input if the input is within the input range. The input range (IR) is determined by *In Max*-*In Min* while the output range (OR) is determined by *Out Max*-*Out Min*. If the input is within the input range then the following is true:

$$Out = (In + In\ Min)(OR/IR) + Out\ Min$$

If the input exceeds, *In Max* then *Out = Out Max*.

If the input is less than, *In Min* then *Out = Out Min*

Tstat	
hvac::Tstat	
Diff	0.00
Is Heating	false
Sp	0.00
Cv	0.00
Out	false
Raise	false
Lower	false

Thermostat — on/off temperature controller.

The configurable float parameter — *Diff* — provides hysteresis and deadband. Another configurable parameter — *Is Heating* — indicates a heating application. *Sp* is the *setpoint* input and *Cv* is the *controlled variable* input. *Raise* and *lower* are outputs.

If $Cv > (Sp + Diff/2)$ then *Lower* is true and will remain true until $Cv < Sp$

If $Cv < (Sp - Diff/2)$ then *Raise* is true and will remain true until $Cv > Sp$

If *Is Heating* is true then *Out = Lower*

If *is Heating* is false then *Out = Raise*

Logic Kit (logic)

ADemux2	
logic::ADemux2	
Out1	0.00
Out2	0.00
In	0.00
S1	false

Analog Demux — Single-input, two-output analog de-multiplexer.

If S1 is false then Out1 = In while Out2 = the last value of In just before S1 changed.

If S1 is true then Out2 = In while Out1 = the last value of In just before S1 changed.

And2	
logic::And2	
Out	false
In1	false
In2	false

Two-input Boolean product — two-input AND gate.

$Out = In1 \cdot In2$

And4	
logic::And4	
Out	false
In1	false
In2	false
In3	false
In4	false

Four-input Boolean product — four-input AND gate.

$Out = In1 \cdot In2 \cdot In3 \cdot In4$

ASW	
logic::ASW	
Out	0.00
In1	0.00
In2	0.00
S1	false

Analog switch — selection between two float variables.

If S1 is false then Out = In1

If S1 is true then Out = In2

ASW4	
logic::ASW4	
Out	0.00
In1	0.00
In2	0.00
In3	0.00
In4	0.00
Starts At	0
Sel	0

Analog switch — selection between four floats.

Configurable integer parameter *Starts At* sets the base selection.

If integer Sel <= Starts At then Out = In1

If integer Sel = Starts At + 1 then Out = In2

If integer Sel = Starts At + 2 then Out = In3

If integer Sel = Starts At + 3 then Out = In4

For all values of Sel that are 4 greater than Starts At then Out = In4

B2P	
logic::B2P	
Out	false
In	false

Binary to pulse — simple mono-stable oscillator (single-shot).

Out = true for one scan on the raising edge of In

BSW	
logic::BSW	
Out	false
In1	false
In2	false
S1	false

Boolean Switch — selection between two Boolean variables.

If S1 is false then Out = In1

If S1 is true then Out = In2

DemuxI2	
logic::DemuxI2B4	
In	0
Out1	true
Out2	false
Out3	false
Out4	false
Starts At	0

Four-output Demux — integer to Boolean de-multiplexer.

If In = StartAt + 0 then Out1 is true, else false

If In = StartAt + 1 then Out2 is true, else false

If In = StartAt + 2 then Out3 is true, else false

If In = StartAt + 3 then Out4 is true, else false

ISW	
logic::ISW	
Out	0
In1	0
In2	0
S1	false

Integer switch — selection between two integer variables.

If S1 is false then Out = In1

If S1 is true then Out = In2

Not	
logic::Not	
Out	true
In	false

Not — inverts the state of a Boolean.

$Out = \bar{In}$

Or2	
logic::Or2	
Out	false
In1	false
In2	false

Two-input Boolean sum — two-input OR gate.

$Out = In1 \mid In2$

Or4	
logic::Or4	
Out	false
In1	false
In2	false
In3	false
In4	false

Four-input Boolean sum — four-input OR gate.

$Out = In1 \mid In2 \mid In3 \mid In4$

Xor	
logic::Xor	
Out	false
In1	false
In2	false

Two-input exclusive Boolean sum — two-input XOR gate.

$Out = In1 \oplus In2 = \bar{In1} \cdot In2 \mid In1 \cdot \bar{In2}$

Application Note — Sedona 1.2 Component Descriptions

Math Kit (math)

Add2	
math::Add2	
Out	0.00
In1	0.00
In2	0.00

Two-input addition — results in the addition of two floats.

$$Out = In1 + In2$$

Add4	
math::Add4	
Out	0.00
In1	0.00
In2	0.00
In3	0.00
In4	0.00

Four-input addition — results in the addition of four floats.

$$Out = In1 + In2 + In3 + In4$$

Avg10	
math::Avg10	
Out	nan
In	0.00
Max Time	0 ms

Average of 10 — sums the last ten floats while dividing by ten thereby providing a running average.

$$Out = (sum\ of\ the\ last\ ten\ values)/ten$$

The float input *In* is sampled once every scan and stored. If the input does not change in value on the next scan, it is not sampled again — unless sufficient time passes that exceeds the internal integer *Max Time* with units of milliseconds. In this instance the input is sampled and treated as another value. Once ten readings occur, the average reading is outputted.

AvgN	
math::AvgN	
Out	0.00
In	0.00
Num Samples To Avg	5
Reset	false

Average of N — sums the last N floats while dividing by N thereby providing a running average.

$$Out = (sum\ of\ the\ last\ N\ values)/N$$

The float input *In* is sampled once every scan and stored regardless whether or not the value changes. Once *Num Samples to Avg* readings occur, the average reading is outputted.

Div2	
math::Div2	
Out	0.00
In1	0.00
In2	0.00
Div0	true

Divide two — results in the division of two floats.

$$Out = In1/In2$$

Div0 = true if *In2* is equal to zero

FloatOf	
math::FloatOffset	
Out	0.00
In	0.00
Offset	0.00

Float offset — float shifted by a fixed amount.

$$Out = In + Offset$$

Offset is a configurable float.

Application Note — Sedona 1.2 Component Descriptions

Max	<input type="checkbox"/>
math::Max	
Out	0.00
In1	0.00
In2	0.00

Maximum selector — selects the greater of two inputs.

Out = Max [In1, In2] where Out, In1 and In2 are floats

Min	<input type="checkbox"/>
math::Min	
Out	0.00
In1	0.00
In2	0.00

Minimum selector — selects the lesser of two inputs.

Out = Min [In1, In2] where Out, In1 and In2 are floats

MinMax	<input type="checkbox"/>
math::MinMax	
Min Out	0.00
Max Out	0.00
In	0.00
R	false

Min/Max detector — records both the maximum and minimum values of a float.

Min Out = Max [In] if R is false

Max Out = Min [In] if R is false

If R is true then Min Out and Max Out = In

Both *Min Out* and *Max Out* are floats — as is *In*.

It may be necessary to reset the component after connecting links to the component.

Mul2	<input type="checkbox"/>
math::Mul2	
Out	0.00
In1	0.00
In2	0.00

Multiply two — results in the multiplication of two floats.

*Out = In1 * In2*

Mul4	<input type="checkbox"/>
math::Mul4	
Out	0.00
In1	0.00
In2	0.00
In3	0.00
In4	0.00

Multiply four — results in the multiplication of four floats.

*Out = In1 * In2 * In3 * In4*

Neg	<input type="checkbox"/>
math::Neg	
Out	0.00
In	0.00

Negate — changes the sign of a float.

Out = - In

Round	<input type="checkbox"/>
math::Round	
Out	0.0
In	0.000
Decimal Places	0

Round — rounds a float to the nearest N places.

For N = -1, Out = In rounded to the nearest tens

For N = 0, Out = In rounded to the nearest units

For N = 1, Out = In rounded to the nearest tenth's

For N = 2, Out = In rounded to the nearest hundredths

For N = 3, Out = In rounded to the nearest thousandths

For positive input values, the output will round up (more positive).

For negative input values, the output will round down (more negative).

Application Note — Sedona 1.2 Component Descriptions

Sub2 	
math::Sub2	
Out	0.00
In1	0.00
In2	0.00

Subtract two — results in the subtraction of two floats.

$$Out = In1 - In2$$

Sub4 	
math::Sub4	
Out	0.00
In1	0.00
In2	0.00
In3	0.00
In4	0.00

Subtract four — results in the subtraction of four floats.

$$Out = In1 - In2 - In3 - In4$$

TimeAvg 	
math::TimeAvg	
Out	0.00
In	0.00
Time	10000 ms

Time Average — the average of a float over a determined time.

$$Out = Avg[In] \text{ over the integer time in milliseconds.}$$

Priority Kit (pricomp)

Priorit	<input type="radio"/>
pricomp::PrioritizedBool	
In2	false
In3	false
In4	false
In5	false
In7	false
In9	false
In10	false
In11	false
In12	false
In13	false
In14	false
In15	false
In16	false
Fallback	false
Out	false

Priority array (Priorit) components exist for Boolean, float and integer variables. Up to 16 levels of priority from In1 to In16 can be assigned. In1 has the highest priority and In16 the lowest. With few exceptions, all can be pinned out. If a priority level is not assigned, it is marked as a Null and therefore ignored. If a Null is inputted to the priority array, the priority array will ignore it and choose the next input in line. The Boolean version of the array has two timer settings — one for minimum active time and one for minimum inactive time. If the highest priority device changes from false to true and then back to false, the priority component will maintain the event for the configured times.

There is a Fallback setting in each array that can be specified. If no valid priority input exists, the Fallback value is transferred to the output.

In16	0
Fallback	0
Out	0

Timing Kit (timing)

DlyOff	
timing::DlyOff	
Out	false
In	false
Delay Time	0.00 s
Hold	0 ms

Off delay timer — time delay from a true to false transition of the input.

For input transitions from false to true, Out = true.

For input transitions from true to false that exceed the Delay Time, Out = false after the delay time.

Hold is a read-only integer that counts down the time. Delay time is in seconds.

DlyOn	
timing::DlyOn	
Out	false
In	false
Delay Time	0.00 s
Hold	0 ms

On delay timer — time delay from a false to true transition of the input.

For input transitions from true to false, Out = false.

For input transitions from false to true that exceed the Delay Time, Out = true after the delay time.

Hold is a read-only integer that counts down the time. Delay Time is in seconds.

OneShot	
timing::OneShot	
Out	false
In	false
Pulse Width	0.00 s
Can Retrig	false

Single Shot — provides an adjustable pulse width to an input transition.

Upon the input transitioning to true, the output will pulse true for the amount of time set in the configurable parameter *Pulse Width*. Time is in seconds. If the configurable parameter *Can Retrig* is set to true, the component will repeat its action on every positive transition of the input. For example in retrigger mode, a one-second *TickToc* connected to a *OneShot* with a 2 second pulse width setting will have the *OneShot* output in a continuous true state due to constant retriggering at a rate faster than the *OneShot* pulse width.

Timer	
timing::Timer	
Out	false
Run	stop
Time	0 s
Left	0 s

Timed pulse — predefined pulse output.

Out becomes true for a predetermined time when Run transitions from false to true. If Run returns to false, then Out becomes false.

Time determines the amount of time the output will be on in seconds.

Types Kit (types)

B2F 	
types::B2F	
Out	0.00
Count	0.00
In1	false
In2	false
In3	false
In4	false
In5	false
In6	false
In7	false
In8	false
In9	false
In10	false
In11	false
In12	false
In13	false
In14	false
In15	false
In16	false

Binary to float encoder — 16-bit binary to float conversion.

Out = encoded value of binary input with In16 being the MSB and In1 being the LSB

Count = sum of the number of active inputs

ConstBo 	
types::ConstBoo	
Out	false

Boolean Constant — a predefined Boolean value.

Out = a Boolean value that is internally configurable

ConstFl 	
types::ConstFloat	
Out	0.00

Float Constant — a predefined float value.

Out = a float value that is internally configurable

ConstIn 	
types::ConstInt	
Out	0

Integer Constant — a predefined integer value.

Out = an integer value that is internally configurable

Application Note — Sedona 1.2 Component Descriptions

F2B	
types::F2B	
In	0.00
Out1	false
Out2	false
Out3	false
Out4	false
Out5	false
Out6	false
Out7	false
Out8	false
Out9	false
Out10	false
Out11	false
Out12	false
Out13	false
Out14	false
Out15	false
Out16	false
Ovrf	false

Float to binary decoder — float to 16-bit binary conversion.

Out1 to Out16 = the 16-bit decoded value of In — with Out16 representing the MSB and Out1 representing the LSB

Ovrf = true when In > 65535

Although the input requires a float, fractional amounts are ignored during the conversion.

F2I	
types::F2I	
In	0.00
Out	0

Float to integer — float to integer conversion.

Out = In except that the output will be a whole number

The fractional amount of the float input will be truncated at the output.

I2F	
types::I2F	
In	0
Out	0.00

Integer to Float — integer to float conversion.

Out = In except that the output will become a float

L2F	
types::L2F	
In	1
Out	1.00

Long to Float — 64-bit signed integer to float conversion.

Out = In except that the output will become a float from a 64-bit signed integer

WriteBo	
types::WriteBool	
In	null
Out	null

Write Boolean — setting a writable Boolean value.

Out = In

Unlike *ConstBo*, this component has an input. Could be helpful when transferring a variable between two wire sheets.

WriteFl	
types::WriteFloat	
In	nan
Out	nan

Write Float — setting a writable float value.

Out = In

Unlike *ConstFl*, this component has an input. Could be helpful when transferring a variable between two wire sheets.

WriteIn	
types::WriteInt	
In	min
Out	min

Write Integer — setting an integer value.

Out = In

Unlike *ConstIn*, this component has an input. Could be helpful when transferring a variable between two wire sheets..

BASremote Service Kit (CControls_BASR8M_Services)

The BASremote service kit allows Sedona application to tie into real world inputs and outputs after object instance configuration. For the BASremote master, object instance assignments must match the I/O channel assignment. For configuring expansion module and virtual points, consult the BASremote User Manual for details. For the online status to revert to true, the point must be properly configured, must be actively scanned by the hardware and not be in a forced state.

InpBool		<input type="radio"/>
CControls BASR8M Services::InpBool		
Out	false	
Online	false	

Input Boolean — BASremote binary input.

Out = value of the real world binary input

InpFlea		<input type="radio"/>
CControls BASR8M Services::InpFloat		
Out	0.00	
Online	false	

Input Float — BASremote analog input or value.

Out = value of the real world analog input

OutBool		<input type="radio"/>
CControls BASR8M Services::OutBool		
In	false	
Online	false	

Output Boolean — BASremote binary output.

In = Boolean variable to be written to a real world output

OutFlea		<input type="radio"/>
CControls BASR8M Services::OutFloat		
In	0.00	
Online	false	

Output Float — BASremote analog output.

In = Float variable to be written to a real world output

OutFlo1		<input type="radio"/>
CControls BASR8M Services::OutFloatCond		
In	0.00	
Out	0.00	
Enable	false	
Online	false	

Output Float Conditional — BASremote conditional analog output.

In = Float variable to be written to a real world output.

Out = Float value currently written to real world output.

Enable = Boolean which indicates whether a write should occur.

True will allow the write to occur and False will inhibit any writes.

Sedona will, normally, write the outputs from its logic every cycle. This can be an issue for some Modbus registers controlled by the BASremote. The writes to these registers can be controlled via the enable signal. If enable is false the Modbus register associated with this component will not be written.

SendEma		<input type="radio"/>
CControls BASR8M Services::SendEmail		
Email Number	5	
In	0.00	
Enable	false	

Send Email — BASremote email alert.

In = Float value to be included in email.

Enable = Boolean used to indicate when to send an email.

Email Number = which email to send (it must match the web configuration).

The BASremote can send an email using this component when the *Enable* signal is true. The email must be configured in the configuration webpage of the BASremote. When the email is sent, the text of the email will contain the current input float value. One Email will be sent on the false-to-true transition of the *Enable* signal.

BASremote Platform Kit (CControls_BASR8M_Platform)

plat	
CControls_BASR8M_Platform::BASremotePlatformService	
Mem Available	13520896

The BASremote platform kit has one component that advises the programmer how much usable memory is available for application programming. With a Linux platform, memory is seldom an issue. The platform kit is found in the service folder.

Application Note — Sedona 1.2 Component Descriptions

BAScontrol20/22 I/O Kit (CControls_BASC20_IO) (CControls_BASC22_IO)

The BAScontrol20 IO kit provides several components necessary to interface Sedona logic to real world inputs and outputs on the BAScontrol20. In addition to 20 real I/O points, the BAScontrol20 accommodates 24 virtual points that can be treated as either inputs or outputs. Universal inputs and virtual points require configuration via a web browser. Other components are included in this kit that are BAScontrol20 hardware dependent.

AO1 – AO4	Analog Output	analog voltage output points
BI1 – BI4	Binary Input	binary input points
BO1 – BO6	Binary Output	binary output points (BO1-B04 with the CControls_BASC20_IO)
UI1 – UI4	Universal Input	binary, analog voltage, thermistor, resistance or accumulator
UI5 – UI8	Universal Input	binary, analog voltage, thermistor or resistance
UC1 – UC4	Retentive Counters	up/down retentive universal counters
VT01 – VT24	Virtual Points	share data with BACnet/IP clients - first eight componenets are retentive
ScanTim	Scan Timer	monitors the time to execute Sedona logic

AO1	<input type="radio"/>
CControls_BASC20_IO::AO1	
Inp F	0.00
Enable	false

AO1 – AO4 Analog Output — analog voltage output point.

Inp F = float value from 0–10 of respective point which translates to 0–10VDC output if Enable is true. If Enable is false, then output is controlled by a BACnet client.

BI1	<input type="radio"/>
CControls_BASC20_IO::BI1	
Out B	false

BI1 – BI4 Binary Input — binary input point.

Out B is true if input point is asserted to common; otherwise Out B is false.

BO1	<input type="radio"/>
CControls_BASC20_IO::BO1	
Inp B	false
Enable	false

BO1 – BO6 Binary Output — binary output point. (BO1-BO4 on BASC20)

Inp B = Boolean value of respective point which will translate to either a contact closure or triac output (on triac models).

If Inp B and Enable are true, the contact closure is made or the triac is turned on. If Enable is false, then output is controlled by a BACnet client.

UI4	<input type="radio"/>
CControls_BASC22_IO::UI4	
Chn Type	Pulse
Out F	0.00
Out B	false
Out I	0
Reset	false

UI1 – UI8 Universal Input — binary, analog voltage, thermistor, resistance or accumulator point (UI1-UI4 can be accumulators).

Out F = float value of respective point if configured for analog input, thermistor, resistance or pulse accumulator.

If point is configured as a thermistor, or resistance, and an out-of-range condition is detected, Out F = the configured Out of Bounds value and Out B = true (thermistor or resistance fault)

Out B = Boolean value if configured for binary input.

Out B is true if input point is asserted to common; otherwise Out B is false.

If in Pulse mode and Reset =true, then Out F = 0.

Out I = the integer representation of the float value.

Application Note — Sedona 1.2 Component Descriptions

VT01 – VT24 Virtual Points — wire sheet read or wire sheet write.

VT01	
CControls_BASC20_IO::VT01	<input type="radio"/>
Chn Type	FloatInput
Reset	false
Float V	0.00
Binary V	false

Virtual points are used to share wire sheet data with a BACnet/IP client. A BACnet/IP client can “read” wire sheet data such as a calculated value or it can “write” to the wire sheet with a set-point or command. Virtual points are first configured from a web page to be a BACnet binary value (BV) or BACnet analog value (AV). The BACnet description field and units of measure can be set as well as the BACnet name which must be unique within the device. Next go to Workbench to change the wire sheet Read or Write directions. The title of the virtual point on the web page will change to Wire Sheet Write or Wire Sheet Read accordingly. The four possibilities are shown on the left labelled as VT01 through VT04.

VT02	
CControls_BASC20_IO::VT02	<input type="radio"/>
Chn Type	FloatOutput
Reset	false
Float V	0.00
Binary V	false

VT01 is configured as analog variable, wire sheet write, which results in the component being a *FloatInput*.

VT03	
CControls_BASC20_IO::VT03	<input type="radio"/>
Chn Type	BinaryInput
Reset	false
Float V	0.00
Binary V	false

VT02 is configured as analog variable, wire sheet read, which results in the component being a *FloatOutput*.

VT03 is configured as binary variable, wire sheet write, which results in the component being a *BinaryInput*.

VT04	
CControls_BASC20_IO::VT04	<input type="radio"/>
Chn Type	BinaryOutput
Reset	false
Float V	0.00
Binary V	false

VT04 is configured as binary variable, wire sheet read, which results in the component being a *BinaryOutput*.

If configured as a *FloatInput*, then *Float V* represents the value written by the BACnet/IP client which can be used by other wire sheet components

If configured as a *FloatOutput*, then *Float V* represents a value from a wire sheet component that can be read by the BACnet/IP client

If configured as a *BinaryInput*, then *Binary V* represents the value written by the BACnet/IP client which can be used by other wire sheet components

If configured as a *BinaryOut*, then *Binary V* represents a value from a wire sheet component that can be read by the BACnet/IP client

Asserting *Reset* will clear the component. It is usually kept in the *False* state.

ScanTim	
CControls_BASC20_IO::ScanTim	
Time Ms	73
Minimum Ms	71
Maximum Ms	77
Average Ms	71

ScanTimer – monitors the execution time of Sedona logic.

The scan timer monitors the current, minimum, maximum and average time it takes to execute a single scan of Sedona logic. All outputs are integers. The average time is based upon the last ten samples. The result of which becomes the first value in the next ten samples. The component can be reset by right-clicking the component and invoking an Action.

UC1	
CControls_BASC20_IO::UC1	
Count	179
Count F	179.00
Ovf	false
Clk	true
Enable	true
Rst	false
C Dwn	false
Hold At Limit	true

UC1 – UC4 — retentive up/down universal counters.

Counts on the false to true transition of *Clk* if *Enable* is *true*. If *C Dwn* is *true*, counting is down until zero is reached. If *C Dwn* is *false*, counting is up to the limit of the counter (2147483647) before it rolls over to zero. If *Hold At Limit* is set to *true*, the counter will stop counting at the value set in the *Limit* slot on the property page. The *Ovf* flag is set *true* when the value of status equals or exceeds the limit value. The output *count* value can be displayed as an integer (*Count*) or a float (*Count F*). *Rst* set to *true* clears the counter and prevents further counting.

BAScontrol20/22 Platform Kit (CControls_BASC20_Platform) (CControls_BASC22_Platform)

plat	
CControls_BASC20_Platform::BASC20PlatformService	
Mem Available	9352

plat	
CControls_BASC22_Platform::BAS22PlatformService	
Mem Available	9352

The BAScontrol20/22 platform kit has only one component that advises the programmer how much usable memory is available for application programming. It is recommended that the usable memory not fall below 8,192 bytes. It can be found in the services folder and can be copied onto the wire sheet. The output type of this component is a *Long*.

Application Note — Sedona 1.2 Component Descriptions

BAScontrol20 Web Kit (CControls_BASC20_Web)

WC01 – WC48 Web Components — share data with BAScontrol20 web pages.

Web components provide a convenient method of sharing data between web pages and the wire sheet without the need of the Workbench tool. In this kit there are 48 web components that must be first configured via web pages. Web components can be configured to read wire sheet data or can write wire sheet data. The four possibilities are shown on the left labeled as WC01 through WC04.

WC01	<input type="radio"/>
CControls_BASC20_Web::WC01	
Wc Type	Input
Flt Val	0.00
Int Val	0
Bin Val	false

WC01 is configured as an input which results in the component being an *Input*.

WC02	<input type="radio"/>
CControls_BASC20_Web::WC02	
Wc Type	FloatOutput
Flt Val	0.00
Int Val	0
Bin Val	false

WC02 is configured as an output float which results in the component being a *FloatOutput*.

WC03	<input type="radio"/>
CControls_BASC20_Web::WC03	
Wc Type	IntegerOutput
Flt Val	0.00
Int Val	0
Bin Val	false

WC03 is configured as output integer which results in the component being an *IntegerOutput*.

WC04	<input type="radio"/>
CControls_BASC20_Web::WC04	
Wc Type	BinaryOutput
Flt Val	0.00
Int Val	0
Bin Val	false

WC04 is configured as an output binary which results in the component being a *BinaryOutput*.

If configured as an Input then Flt Val, Int Val, and BinVal represents the value written by a web page which can be used by other wire sheet components

If configured as a FloatOutput, then Flt Val represents a value from a wire sheet component that can be read by a web page

If configured as an IntegerOutput, then Int Val represents a value from a wire sheet component that can be read by a web page

If configured as a BinaryOutput, then Bin Val represents a value from a wire sheet component that can be read by a web page

Simplified Psychrometric Chart

A simplified psychrometric chart greatly removes the detail of a professional chart. On the X-axis is the dry-bulb temperature with a typical range from 32°F to 120°F. This is the same temperature you measure with a thermometer or wall-mounted thermostat. Lines of constant dry-bulb temperature are for all practical purposes vertical. On the Y-axis is the humidity ratio (lbw/lba) in lbs-water vapor to lbs-air ranging from zero to over 0.028. Lines of constant humidity ratio are horizontal. The left curved heavy line is called the saturation line indicating 100% saturation of water vapor or 100% relative humidity. Curves of lesser relative humidity would exist to the right of the saturation line. Along the saturation line you can

determine both dew point temperature and wet-bulb temperature although their lines of constant temperature are different. For dew point, the lines are horizontal while the lines of constant wet-bulb are diagonal and almost parallel with lines of constant enthalpy.

Looking at the PsychrE component and the simplified chart we can study one example. Notice in the component that the two inputs are 70°F dry-bulb and 50% relative humidity. With these two values a single point on the psychrometric chart can be located. If you follow the horizontal line to the left you can determine the dew point temperature and to the right the humidity ratio. If you follow the diagonal line to the upper-left you can learn the wet-bulb and enthalpy values. We still have not determined the saturation pressure or the vapor pressure but these values can be derived with help from the humidity ratio. The PsychrE can make the calculations in the English system and the PsychrS can make the calculations in the SI system. Although simple conversions can be made between the two systems or to reflect the output values in different units of measure, be careful when working with enthalpy. With the English system, the change in enthalpy is referenced to a 0°F while in the SI system the reference is 0°C so a straight forward conversion between the two systems is not possible. Also note the limited range of the two psychrometric components. Both components are limited to an equivalent input range of 0-120°F dry-bulb and 10-100% relative humidity.

SCLatch	
CControls_Function::SCLatch	<input type="radio"/>
Set	false
Clear	false
Out	false
Out Not	true

Set/Clear Latch – single-bit level-triggered single-bit data storage

The following logic applies to the state of Set or Clear:

If Set is true and Clear is false, then Out = true

If Clear is true, then Out = false regardless of the state of Set

Out Not = Out
